# ARTIFICIAL INTELLIGENCE

Particle Swarm Optimization Ant Colony Optimization

### Local search

- Simple local search a single neighbour state is retained
  - □ Hill climbing → selects the best neighbour
  - □ Simulated annealing → selects probabilistically the best neighbour
  - $\square$  Tabu search  $\rightarrow$  retains the list of visited solutions

- Beam local search more states are retained (a population of states)
  - Evolutionary algorithms
  - Particle swarm optimisation
  - Ant colony optimization

# Nature-inspired algorithms

- Swarm intelligence (collective intelligence)
  - A group of individuals that interact in order to achieve some objectives by collective adaptation to a global or local environment
  - A computational metaphor inspired by
    - Birds" flying (V shape)
    - Ants that are searching food
    - Bees" swarms that are constructing their nest
    - Schools of fish

#### Because:

- Control is distributed among more individuals
- Individuals local communicate
- system behaviour transcends the individual behaviour
- System is robust and can adapt to environment changes
- Social insects (2% of total)
  - Ants
    - 50% of social insects
    - 1 ant has ~ 1mg → total weight of ants ~ total weight of humans
    - Live for over 100 millions of years (humans live for over 50 000 years)
  - Termites
  - Bees

# Nature-inspired algorithms

#### Swarm (Group)

- More individuals, apparently un-organised, that are moving in order to form a group, but each individual seems to move in a particular direction
- Inside the group can appear some social processes
- The collection is able to do complex tasks
  - Without a guide or an external control
  - Without a central coordination
- The collection can have performances better than the independent individuals

#### □ Collective adaptation → self-organisation

- Set of dynamic mechanisms that generates a global behaviour as a result of interaction among individual components
- Rules that specify this interaction are executed based on local information only, without global references
- Global behaviour is an emergent property of the system (and not one external imposed)

### **PSO**

- Theoretical aspects
- Algorithm
- Example
- Properties
- Applications

- → Proposed by
  - Kennedy and Eberhart in 1995
  - Inspired by social behaviour of bird swarms and school of fish

- → Search is
  - Cooperative, guided by the relative quality of individuals
- → Search operators
  - A kind of mutation

#### Special elements

- Optimisation method based on:
  - □ Populations ( ≈ EAs) of particles (≈ chromosomes) that search the optimal solution
  - Cooperation (instead of concurrence, like in EAs case)

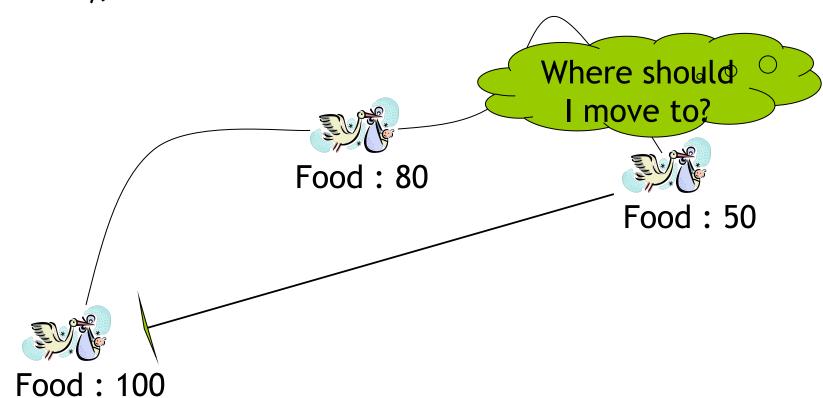

#### Each particle

- moves (in the search space) and has a velocity (velocity ≈ movement, because the time is discrete)
- Retains the place where it has obtained the best results
- Has associated a neighbourhood of particles

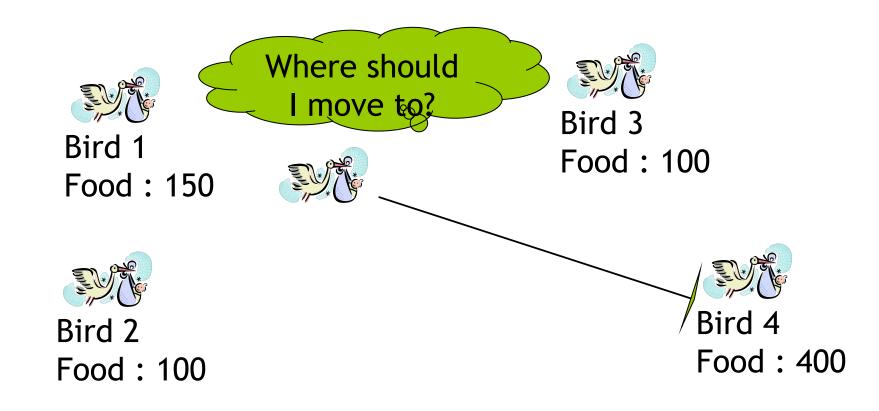

#### Particles cooperate

- Exchange information among them (regarding the discovering performed in the places already visited)
- Each particle knows the fitness of neighbours such as it can use the position of the best neighbour for adjusting its velocity

Main idea: cognitive behaviour  $\rightarrow$  an individual remembers past knowledge (has memory)

Main idea: social behaviour  $\rightarrow$  an individual relies on the knowledge of other members of the group

#### General sketch

- 1. Creation of the initial population of particles
  - Random positions
  - 2. Null/random velocities
- Evaluation of particles
- 3. For each particle
  - Update the memory
    - Identify the best particle of the swarm  $(g_{Best})$  / of the current neighbourhood  $(I_{Best})$
    - Identify the best position (with the best fitness) reached until now  $p_{Rest}$
  - Update the velocity
  - Update the position
- If the stop conditions are not satisfied, go back to step2; otherwise STOP.

# Creation of the initial population of particles

- Each particle has associated
  - A position possible solution of the problem
  - A velocity changes a position into another position
  - A quality function (fitness)

#### Each particle has to:

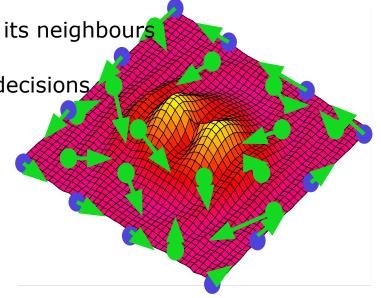

Interact (exchange information) with its neighbours

Memorise a previous position

Use the information in order to take decisions

#### Initialisation of particles

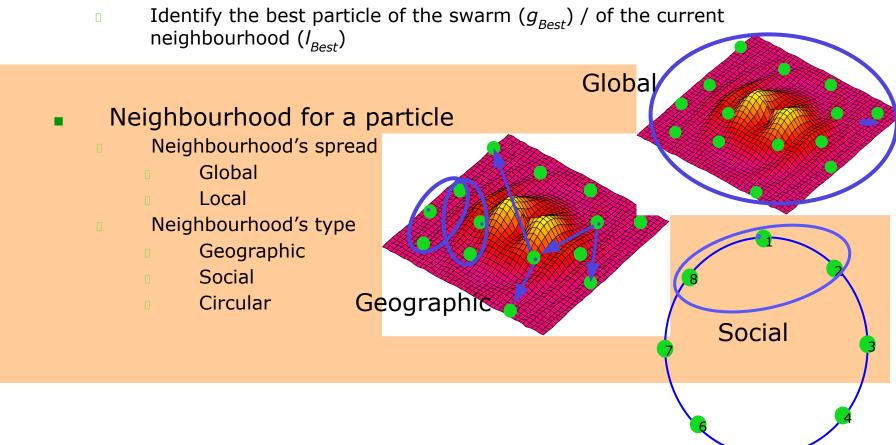

- Random positions
- Null/random velocities

- 2. Evaluation of particles
- Depends on problem

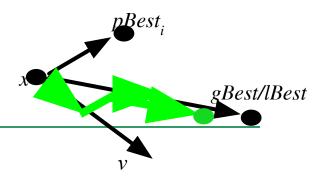

### 3. For each particle $p_i$

Update the memory

### 3. For each particle $p_{_i}$

- Update the memory
  - Identify the best particle of the swarm  $(g_{\textit{Best}})$  / of the current neighbourhood  $(I_{\textit{Best}})$
  - Identify the best position (with the best fitness) reached until now  $p_{{\scriptscriptstyle Best}}$

- 3. For each particle  $p_{_{i}}$ 
  - Update the velocity  $\mathbf{v_i}$  and position  $\mathbf{x_i} = (x_{i1}, x_{i2}, ..., x_{iD})$  (on each dimension)
    - $v_{id} = w * v_{id} + c_1 * rand() * (p_{Best d} x_{id}) + c_2 * rand() * (g_{Best d} x_{id})$
    - $x_{id} = x_{id} + v_{id}$
    - where:
      - i=1,N (N total number of particles/swarm size);
      - d = 1,D
      - w inertia coefficient (Shi, Eberhart)
        - $w*v_{id}$  inertial factor  $\rightarrow$  forces the particle to move in the same direction until now (audacious)
        - Balance the search between global exploration (large w) and local exploration (small w)
        - Can be constant or descending (while the swarm is getting old)
      - c, cognitive learning coefficient
        - $c_1*rand()*(p_{Best\;d}-x_{id})$  cognitive factor  $\to$  forces the particle to move towards its best position (conservation)
      - $c_2$  social learning coefficient
        - $c_2$ \* rand() \*  $(g_{Bestd} x_{id})$  social factor  $\rightarrow$  forces the particle to move towards the best neighbour (follower)
      - $c_1$  and  $c_2$  can be equal or different ( $c_1 > c_2 i c_1 + c_2 < 4 Carlise, 2001)$
    - Each component of velocity vector must belong to a given range  $[-v_{max'}, v_{max}]$  in order to keep the particles inside the search space

#### PSO principles:

- Proximity the group has to performed computing in space and time
- Quality the group has to be able of answering to the quality of environment
- Stability the group has not to change its behaviour at each environment change
- Adaptability the group has to be able of changing its behaviour when the cost on change is not prohibit

#### Differences from EAs:

- There is no recombination operator information exchange takes place based on particle's experience and based on the best neighbour (not based on the parents selected based on quality only)
- Position update ~ mutation
- Selection is not utilized survival is not based on quality (fitness)

#### PSO versions

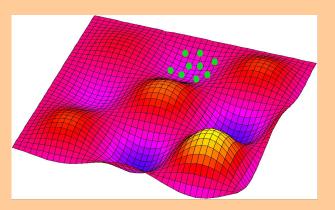

- PSO binary and discrete
- PSO with more social learning coefficients
- PSO with heterogeneous particles
- Hierarchic PSO

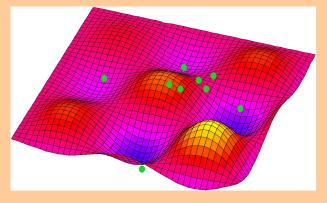

- PSO discrete (binary)
  - PSO version for a discrete search space
  - Position of a particle
    - □ Possible solution of the problem → binary string
    - Changes based on the velocity of particle
  - Velocity of a particle
    - Element from a continuous space
    - Changes based on standard PSO principles
    - Can be viewed as changing probability of the corresponding bit from the particle's position

$$x_{ij} = \begin{cases} 1, & \text{if } \tau < s(v_{ij}) \\ 0, & \text{otherwise} \end{cases}, \text{ where } s(v_{ij}) = \frac{1}{1 + e^{-v_{ij}}}$$

#### Risks

- Particles has the trend to group in the same place
  - To rapid convergence and the impossibility to escape from local optima
  - Solution:
    - Re-initilaisation of some particles

Particles move through infeasible regions

- Analysis of PSO algorithm
  - Dynamic behaviour of the swarm can be analysed by 2 index:
    - Dispersion index
      - Measures the spreading degree of particle around the best particle of the swarm
      - Average of absolute distances (on each dimension) between each particle and the best particle of the swarm
      - Explains the cover degree (small or spread) of the search space
    - Velocity index
      - Measures the moving velocity of the swarm into a iteration
      - Average of absolute velocities
      - Explain how the swarm moves (aggressive or slow)

### PSO – applications

- Control and design of antenna
- Biological, medical and pharmaceutical applications
  - Analysis of tremor in Parkinson's disease
  - Cancer Classification
  - Prediction of protein structure
- Network communication
- Combinatorial optimisation
- Financial optimisation
- Image and video analyse
- Robotics
- Planning
- Network security, intrusion detection, cryptography
- Signal processing

### ACO

- Theoretical aspects
- Algorithm
- Example
- Properties
- Applications

#### Proposed

- By Colorni and Dorigo in 1991 for solving discrete optimisation problems – TSP – as a comparison for EAs
- Inspired by social behaviour of ants that search a path from their nest and food
- Why ants?
  - Colony system (from several ants to millions of ants)
  - Labor division
  - Social behaviour is very complex

#### Search ■

- Cooperative, guided by the relative quality of individuals
- Search operators
  - Constructive ones, adding elements in solution

#### Special elements

- The optimisation problem must be transformed into a problem of identifying the optimal path in an oriented graph
- Ants construct the solution by walking through the graph and put pheromones on some edges
- Optimisation method based on
  - Ant colonies (≈EAs) that search the optimal solution
  - Cooperation (instead of concurrence like in EAs)
- > Each ant:
  - Moves (in the search space) and put some pheromones on its path
  - Memorises the path
  - Selects the path based on
    - The existing pheromones on that path
    - Heuristic information associated to that path
  - Cooperates with other ants through the pheromone trail (that corresponds to a path) that
    - Depends on the solution quality
    - Evaporates while the time is passing

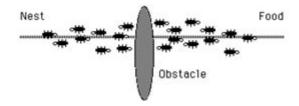

- Natural ants
  - An ant colony start to search some food

#### Natural ants

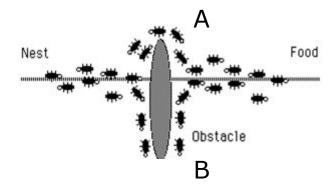

- An ant colony start to search some food
- At a moment, an obstacle appears

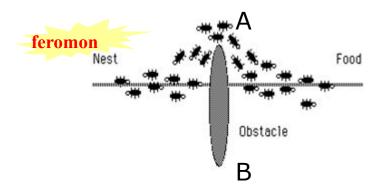

#### Natural ants

- An ant colony start to search some food
- At a moment, an obstacle appears
- The ants will surround the obstacle either on path A or path B

#### Natural ants

- An ant colony start to search some food
- At a moment, an obstacle appears
- The ants will surround the obstacle either on path A or path B
- Because the path A is shorter, the ants of this path will performed more rounds and, therefore, will put more pheromones
- Pheromone concentration will quickly increase on path A (relative to path B) such as the ants from path B will re-oriented to path A
- Because the ants do not follow path B and because the pheromone trail evaporates, the trail of ants from path B will disappear
- Therefore, the ants will take the shortest path (path A)

- Artificial ants look like natural ants
  - Walk from their nest towards food
  - Discover the shortest path based on pheromone trail
    - Each ant performed random moves
    - Each ant put some pheromone on its path
    - Each ant detects the path of "boss ant" and tends to follow it
    - Increasing the pheromone of a path will determine to increase the probability to follow that path by more ants
- But they have some improvements:
  - Has memory
    - Retains performed moves → has a proper state (retaining the history of decisions)
    - Can come back to their nest (based on pheromone trail)
  - Are not completely blind can appreciate the quality of their neighbour space
  - Perform move in a discrete space
  - Put pheromone based on the identified solution, also

- Pheromone trail plays the role of
  - A collective, dynamic and distributed memory
  - A repository of the most recent ants' experiences of searching food
- Ants can indirectly communicate and can influence each-other
  - By changing the chemical repository
  - In order to identify the shortest path from nest to food

### ACO – algorithm

- □ While iteration < maximum # of iterations
  - 1. Initialisation
  - 2. While # of steps required to identify the optimal solution is not performed
    - For each ant of the colony
      - Increase the partial solution by an element (ant moves one step)
      - Change locally the pheromone trail based on the last element added in solution
  - 3. Change the pheromone trail on the paths traversed by
    - all ants/the best ant
  - 4. Return the solution identified by the best ant

# ACO – algorithm

#### 3 versions – differences:

- Rules for transforming a state into another state (moving rules for ants)
- Moment when the ants deposit pheromones
  - While the solution is constructed
  - At the end of solution's construction
- Which ant deposits pheromones
  - All the ants
  - The best ant only

#### Versions :

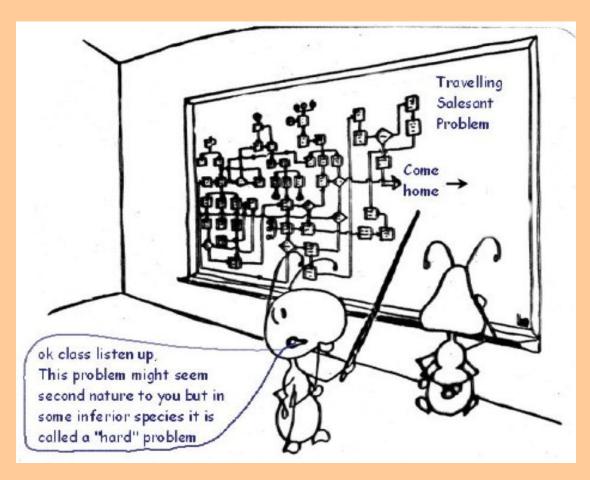

- Ant system (AS)
  - All the ants deposit pheromones after a solution is complete constructed (global collective update)
- MaxMin Ant System (MMAS) ≈ AS, but
  - The **best** ant only deposits pheromones **after** a solution is **complete** constructed (global update of the leader)
  - Deposited pheromones is **limited** to a given range
- Ant Colony System (ACO) ≈ AS, but
  - All the ants deposit pheromones at each step of solution construction (collective local update)
  - The **best** ant only deposits pheromone after the solution is complete constructed
  - (global update of the leader)

### ACO – example

Travelling salesman problem - TSP

Finds the shortest path that visits only once all the n given

cities.

### ACO – example

#### 1. Initialization:

- t := 0 (time)
- For each edge (i,j) 2 elements are initialised:
  - $au_{ii}^{(t)} = c$  (intensity of pheromone trail on edge (I,j) at time t)
  - $\Delta \tau_{ii} = 0$  (quantity of pheromone deposited on edge (i,j) by all the ants)
- m ants are randomly places in n city-nodes ( $m \le n$ )
- Each ant updates its memory (list of visited cities)
  - Adds in the list the starting city

- While # of steps required to identify the optimal solution is not performed (# of steps = n
  - For each ant of the colony
    - Increase the partial solution by an element (ant moves one step)

      Each ant k (from city i) selects the next city j:

where:

$$p_{ij}^{k}(t) = \begin{cases} \frac{\left[\tau_{ij}^{(t)}\right]^{\alpha}\left[\eta_{ij}\right]^{\beta}}{\sum\limits_{s-allowed_{k}(t)}\left[\tau_{is}\right]^{\alpha}\left[\eta_{is}\right]^{\beta}}, & j-allowed \\ 0, & otherwise \end{cases}$$

- $p_{ij}^k$  probability of transition of ant k from city i to city j
- visibility from city I towards city j (attractive choice of edge (i,j))
- allowed, cities that can be visited by ant k at time t
- a controls the trail importance (how many ants have visited that edge)
- $\beta$  controls the visibility importance (how close is the next city)

- While # of steps required to identify the optimal solution is not performed
  - For each ant of the colony
    - Increase the partial solution by an element (ant moves one step)
    - Change locally the pheromone trail based on the last element added in solution

$$\tau_{ij}^{(t+1)} = (1 - \varphi)\tau_{ij}^{(t)} + \varphi * \tau_0$$

- where:
  - $\varphi$  pheromone degradation coefficient;  $\varphi \in [0,1]$ ; for  $\varphi = 0 \rightarrow AS/MMAS$ , otherwise ACO
  - $\tau_0$  initial value of pheromone
  - (i,j) last edge visited by ant

- Change the pheromone trail from
- Paths covered by all ants (AS)
  - For each edge
    - Compute the unit quantity of pheromones put by the k<sup>th</sup> ant on edge
       (i,j)
      - $\Delta \tau_{ij}^{k-1} = \begin{cases} Q \\ L_k \\ 0 \end{cases}$  ant used the edge (i,j)
      - $\cdot$  Q quantity of pheromone deposited by an ant.
      - $L_{\nu}$  length (cost) of tour performed by the  $k^{\text{th}}$  ant
    - Compute the total quantity of pheromone from edge (ij)  $\Delta au_{ij} = \sum_{k=1}^m \Delta au_{ij}^k$
    - Compute the intensity of pheromone trail as a sum of old pheromone evaporation and the new deposited pheromone

$$\tau_{ij}^{(t+n)} = (1-\rho) * \tau_{ij}^{(t)} + \Delta \tau_{ij}$$

• Where  $\rho$  (0< $\rho$ <1) – evaporation coefficient of pheromone trail from a complete tour to another complete tour

- Change the pheromone trail from 3.
  - The best path (ACO)
  - The best path of the best ant (MMAS)
  - For each edge of the best path
    - Compute the unit quantity of pheromone deposited by the best ant on edge (ij)

$$\Delta au_{ij} = rac{1}{L_{best}}$$

- L<sub>best</sub> length (cost) of the best path Of current iteration

  - Over all executed iteration (until that time)
- Compute the intensity of pheromone trail as sum of old pheromone evaporation and the new deposited pheromone
  - Where  $\rho$  (0< $\rho$ <1) – evaporation coefficient of pheromone trail from a complete tour to another complete tour
  - τ<sub>min</sub> şi τ<sub>max</sub> limits (inferior and superior) of pheromone;

• For 
$$\tau_{min} = -\infty$$
 and  $\tau_{max} = +\infty \rightarrow ACO$ , otherwise MMAS

$$\tau_{ij}^{(t+n)} = \left[ (1-\rho) * \tau_{ij}^{(t)} + \rho * \Delta \tau_{ij}^{best} \right]_{\tau_{\min}}^{\tau_{\max}}$$

### ACO – properties

#### Properties

- Iterative algorithm
- Algorithm that progressively constructs the solution based on
  - Heuristic information
    - Pheromone trail
- Stochastic algorithm

#### Advantages

- Run continuous and real-time adaptive change input
  - Ex. for TSP the graph can be dynamically changed
- Positive feedback helps to quickly discovering of solution
- Distributed computing avoids premature convergence
- Greedy heuristic helps to identify an acceptable solution from the first stages of search
- Collective interaction of individuals

#### Disadvantages

- Slowly convergence vs other heuristic search
- For TSP instances with more than 75 cities it finds weak solutions
- In AS there is no central process to guide the search towards good solutions

### ACO – applications

- Optimal paths in graphs
  - Ex. Traveling Salesman Problem
- Problems of quadratic assignments
- Problems of network optimisation
- Transport problems

### Review

#### PSO

- Beam local search
- Possible solutions → particles that have:
  - A position in the search space
  - A velocity
- Cooperative and perturbative search based on:
  - Position of the best particle of the swarm
  - Best position of particle (particle has memory)

#### 

- Beam local search
- Possible solutions → ants that have:
  - Memory retain steps of solution construction
  - Smell take decisions based on pheromones deposited by other ants (social, collective, collaborative behaviour)
- Cooperative and constructive search

# Thank you!
